The AAL conducted a data enhancement project for archaeological resources in Jasper County, Indiana funded by a FY2014 Historic Preservation Fund Grant. This project focused on major waterways such as the Iroquois and Kankakee Rivers in the southern half of the county. Approximately 900 acres of agricultural land were surveyed, identifying 112 new archaeological sites. The survey recovered 209 prehistoric artifacts and 367 historic artifacts. Cultural periods that are represented in the artifact assemblage include Middle Archaic, Late Archaic, and Late Woodland/Late Prehistoric components that were documented from the precontact era, in addition to Historic components. Two sites were recommended for additional research and are potentially eligible for the National Register of Historic Places.

Introduction

The AAL was awarded a FY2014 Historic Preservation Fund (HPF) Grant to survey areas in the southern portion of Jasper County, Indiana. The project involved a pedestrian survey of approximately 900 acres of agricultural land. The main goal of the project was to increase the site database, build on a previous HPF grant survey (Smith and Sanchez 2013), and add to the understanding of the Early Woodland and Middle Archaic periods. The project included a collection visit to the previously surveyed area and a pedestrian survey to increase the site database. The survey was conducted by a team of archaeologists including Scott Smith and Benjamin Sanchez.

Methods

Of the 112 archaeological sites, 59 had unidentified Prehistoric components (MacLeod et al. 2015:Table 20). The identified precontact components consisted of Middle Archaic, Late Archaic, and Late Woodland. The frequency of diagnostic Prehistoric components encountered in the project area in a result of survey was similar to what had already been identified in Jasper County. This includes higher representations of Late Archaic, and Late Woodland, but is in slight contrast to the relatively low representation of Middle Archaic. It is also in keeping with no items dating to the Paleoindian, Early Archaic, Early Woodland, or Middle Woodland. This trend with previously recorded sites in Jasper County stands partially in contrast to the information gleaned from the collector visit particularly early with respect to relatively high frequency of Paleoindian and Early Woodland materials. Two prehistoric scatters discovered as a result of this project (12-Js-279 and 12-Js-340) were recommended for further investigation.

A private collection was also documented in a version of the protocol that eventually became the COADS protocol (see Olson et al. this session). All available diagnostics were sorted by base type, identified by raw material type, and 2D scanned on both sides. A small sample for artifacts were 3D scanned with a NextEngine HD laser scanner.

Results

A total of 431 diagnostic artifacts and tools were examined. The majority (55.22%) were classified as "unidentified" material due to time constraints. The remainder displayed a source breakdown comparing to the materials recovered from the survey. An overwhelming majority of identified artifacts were of Mississippian age (33.41%, or ~76% of identifiable), 9.05% of the collection (~21% of identifiable) was Silurian in age, and 0.40% (~1% of identifiable) of the material was Pennsylvanian. An additional 0.70% (~1.6% identifiable) was identified as shale and quartzite. Fifteen fluted/Paleoindian points of various cherts were documented (3.48%). This may indicate a strong, as of yet, undocumented Paleoindian presence in Jasper County, or possibly may be collector bias. As for the other artifact classes in the general collection (above left), side notched points (n=89) were the most common, possibly indicating a strong Middle Archaic presence. Corner notched points (n=55) were the second most represented group. Stemmed points (n=47), common among Late Archaic through Early Woodland cultures, such as Adena, were also well represented. The predominance of side notched points is surprising given the near absence of Middle Archaic sites in SHAARD. The proportion of side notched points is roughly consistent with the survey (though n=1). These numbers should be viewed cautiously as there are a relatively low number of diagnostic prehistoric sites in Jasper County. This means that only coarse comparisons based on these samples is warranted. A small prehistoric ceramic collection was also in the private collection (above right). This included three dentate stamped sherds, multiple incised sherds, and one Early Woodland sherd. The collection also included several boxes of grooved axes, a bannertone, a partial biface, several gorge fragments, a historic ceramic stopper, several 19th century pipes, a few pther-like buttons, historic bullets, and historic metal including a musket ball.

Unidentified Prehistoric scatters. The Historic components yielded the majority of the artifacts (n=307) recovered during the project. Though several moderately sized historic scatters were encountered during this survey, no sites with historic components were considered to meet the NRHP criteria.

Survey Summary

This project targeted the Iroquois River drainage in the southern half of Jasper County, Indiana, a data deficient county. Similar to results of previous surveys conducted in and immediately surrounding Jasper County (see Looeewirk et al., Smutzko et al., and Thompson et al., this symposium), there is a dearth of artifacts in the areas surveyed. The generally expansive pre-colonial wetlands heavily restricted the population to concentrate activities to select well drained features. The four prehistoric diagnostics are from the Middle Archaic, Late Archaic, and Late Woodland/Late Prehistoric periods. The presence of these materials shows that the area in which they were recovered was habitable during those time periods. The survey recovered 516 artifacts consisting of 209 prehistoric artifacts (one per 4.32 acres) and 307 historic artifacts (one per 2.93 acres). Two sites, both lithic scatters, were recommended for further investigation.

Collector Visit

To the aforementioned Kankakee and Iroquois waterways. The survey recovered 209 prehistoric artifacts and tools. The presence of these materials shows that the area in which they were recovered was habitable during those time periods. The survey recovered 516 artifacts consisting of 209 prehistoric artifacts (one per 4.32 acres) and 307 historic artifacts (one per 2.93 acres). Two sites, both lithic scatters, were recommended for further investigation.

Acknowledgments

This project has been funded in part by a grant from the U.S. Department of the Interior, National Park Service’s Historic Preservation Fund administered by the Indiana Department of Natural Resources, Division of Legacy Preservation and Stewardship, Wildlife and Heritage Division, for financial assistance for the enhancement project, Antiquities Program, and cultural resources in the State of Indiana. The contents and opinions contained in the publication do not necessarily reflect the views or policies of the U.S. Department of the Interior. The project includes information on land use, soil, climate, vegetation, cultural resources, and history. The information provided here is for informational purposes only.
